Abundant Number

An abundant number is a number for which the sum of its proper divisors is greater than the number itself. Proper divisors of the number are those that are strictly lesser than the number.

Input Format:

Take input an integer from stdin **Output**

Format:

Return Yes if given number is Abundant. Otherwise, print No **Example**

input:

12

Output:

Yes

Explanation

The proper divisors of 12 are: 1, 2, 3, 4, 6, whose sum is 1 + 2 + 3 + 4 + 6 = 16. Since sum of proper divisors is greater than the given number, 12 is an abundant number.

Example input:

13

Output:

No

Explanation

The proper divisors of 13 is: 1, whose sum is 1. Since sum of proper divisors is not greater than the given number, 13 is not an abundant number.

For example:

Test	Result
print(abundant(12))	Yes
print(abundant(13))	No

Program:

```
def abundant(n):

    l,s=[],0    for i in

range(1,int(n//2)+1):

if(n%i==0):
```

l.append(i)

for i in l:

s+=i   if(s>n):

return("Yes")

else:

return("No")

Output:

	Test	Expected	Got	
✔	`print(abundant(12))`	Yes	Yes	✔
✔	`print(abundant(13))`	No	No	✔

Passed all tests! ✔

Correct
Marks for this submission: 1.00/1.00.

Automorphic number or not

An automorphic number is a number whose square ends with the number itself. For example, 5 is an automorphic number because 5*5 =25. The last digit is 5 which same as the given number.

If the number is not valid, it should display "Invalid input".
If it is an automorphic number display "Automorphic" else display "Not Automorphic".

Input Format:
Take a Integer from Stdin Output
Format:
Print Automorphic if given number is Automorphic number, otherwise Not Automorphic
Example input: 5 Output: Automorphic Example input: 25 Output: Automorphic
Example input: 7 Output: Not Automorphic For example:

Test   Result
print(automorphic(5))   Automorphic

.

Program:

def automorphic(n):

   a=str(n*n)   if(int(a[-

1])==n):

     return("Automorphic")

   else:

     return("Not Automorphic")

Output:

	Test	Expected	Got	
✔	print(automorphic(5))	Automorphic	Automorphic	✔
✔	print(automorphic(7))	Not Automorphic	Not Automorphic	✔

Passed all tests! ✔

Correct
Marks for this submission: 1.00/1.00.

Check Product of Digits

Write a code to check whether product of digits at even places is divisible by sum of digits at odd place of a positive integer.

Input Format:

Take an input integer from stdin.

Output Format:

Print TRUE or FALSE.

Example Input:

1256

Output:

TRUE

Example Input:

1595

Output:

FALSE

For example:

Test	Result
print(productDigits(1256))	True
print(productDigits(1595))	False

Program:

```
def productDigits(n):
    a=str(n)    s,p=0,1    for

i in range(0,len(a),2):

        s+=int(a[i])    for i in

range(1,len(a),2):
```

```
    p*=int(a[i])
 if(p%s==0):
    return("True")
else:
return("False")
```

Output:

Christmas Discount

An e-commerce company plans to give their customers a special discount for Christmas.

They are planning to offer a flat discount. The discount value is calculated as the sum of all the prime digits in the total bill amount.

Write an python code to find the discount value for the given total bill amount.

Constraints

$1 <= orderValue < 10e^{100000}$

Input

The input consists of an integer orderValue, representing the total bill amount.

Output

Print an integer representing the discount value for the given total bill amount.

Example Input

578

Output

12

For example:

Test	Result
print(christmasDiscount(578))	12

Program:

```
def christmasDiscount(n):

    res=0

while n!=0:

rem=n%10

    flag=0       for i in

range(1,rem+1):          if

rem%i==0:

          flag+=1

if flag==2:

res=res+rem

n=n//10

    return res
```

Output:

Ex. No.   :   **Date:**

Register No.:   **Name:**

	Test	Expected	Got	
✔	`print(christmasDiscount(578))`	12	12	✔

Passed all tests! ✔

Correct
Marks for this submission: 1.00/1.00.

Coin Change

complete function to implement coin change making problem i.e. finding the minimum number of coins of certain denominations that add up to given amount of money. The only available coins are of values 1, 2, 3, 4 Input Format:

Integer input from stdin.

Output Format:

return the minimum number of coins required to meet the given target.

Example Input:

16

Output:

4

Explanation:

We need only 4 coins of value 4 each Example

Input:

25

Output:

7

Explanation:

We need 6 coins of 4 value, and 1 coin of 1 value

Program:

def coinChange(amount):   #

Available coin denominations

   coins = [1, 2, 3, 4]

   # Initialize a list to store the minimum number of coins for each amount from 0 to the target amount   dp = [float('inf')] * (amount + 1)

   dp[0] = 0 # Base case: 0 coins needed to make amount 0

```python
    # Iterate through all amounts from 1 to the target amount
for i in range(1, amount + 1):

    # Iterate through all available coin denominations
for coin in coins:

    # If the current coin denomination is less than or equal to the
current amount

    if coin <= i:

            # Update dp[i] to be the minimum between its current
value and dp[i - coin] + 1                dp[i] = min(dp[i], dp[i - coin] + 1)

    # The result is stored at dp[amount]
return dp[amount]     amount =

int(input())

print(coinChange(amount))
```

Output:

	Test	Expected	Go
✔	print(coinChange(16))	4	4

Passed all tests! ✔

Correct

Marks for this submission: 1.00/1.00.

.

Difference Sum

Given a number with maximum of 100 digits as input, find the difference between the sum of odd and even position digits.

Input Format:

Take a number in the form of String from stdin.

Output Format:

Print the difference between sum of even and odd digits Example

input:

1453

Output:

1

Explanation:

Here, sum of even digits is $4 + 3 = 7$ sum

of odd digits is $1 + 5 = 6$.

Difference is 1.

Note that we are always taking absolute difference

Program:

def differenceSum(n):

   a=[]   b=[]   k=str(n)

for i in range(len(k)):

if int(i)%2==0:

      a.append(int(k[i]))

      else:

      b.append(int(k[i]))

s=sum(b)

   r=sum(a)

j=s-r

return j

Output:

	Test	Expected	Got	
✔	`print(differenceSum(1453))`	1	1	✔

Passed all tests! ✔

.

Ugly number

A number is considered to be ugly if its only prime factors are 2, 3 or 5. [1,
2, 3, 4, 5, 6, 8, 9, 10, 12, 15, …] is the sequence of ugly numbers.
Task: complete the function which takes a number n as input and checks if it's an ugly
number. return ugly if it is ugly, else return not ugly Hint:
An ugly number U can be expressed as: U = 2^a * 3^b * 5^c, where a, b and c are
nonnegative integers. **For example:**

Test	**Result**
print(checkUgly(6))	ugly
print(checkUgly(21))	not ugly

Program:

def checkUgly(n):   **for i in**

range(n):   **for j in range(n):**

for k in range(n):

if(n==(2**i)+(3**j)+(5**k)):

      return("ugly")

    return("not ugly")

Output:

	Test	Expected	Got	
✔	`print(checkUgly(6))`	ugly	ugly	✔
✔	`print(checkUgly(21))`	not ugly	not ugly	✔

Passed all tests! ✔

Correct

Marks for this submission: 1.00/1.00.
